The Solar Polar Imager Mission

- SPI mission is one of several Sun-Earth Connection solar sail roadmap missions currently envisioned by NASA
- Objectives:
 - To investigate the global structure and dynamics of the solar corona
 - To reveal the secrets of the solar cycle and the origins of solar activity
- Target orbit is a heliocentric circular orbit at 0.48 AU with an inclination of 75 deg
 - ▶ 3:1 resonance with Earth
 - different target inclinations have been considered in various previous studies
- Similar solar sail mission, called Solar Polar Orbiter (SPO), is studied by ESA

The Non-Perfectly Reflecting Solar Sail

The non-perfectly reflecting solar sail model parameterizes the optical behavior of the sail film by the optical coefficient set

$$\mathcal{P} = \{\rho, \boldsymbol{s}, \varepsilon_{\mathrm{f}}, \varepsilon_{\mathrm{b}}, B_{\mathrm{f}}, B_{\mathrm{b}}\}$$

The optical coefficients for a solar sail with a highly reflective aluminum-coated front side and with a highly emissive chromium-coated back side are:

$$\mathcal{P}_{\mathsf{AI|Cr}} = \{
ho = 0.88, s = 0.94, arepsilon_{\mathsf{f}} = 0.05, \ arepsilon_{\mathsf{b}} = 0.55, B_{\mathsf{f}} = 0.79, B_{\mathsf{b}} = 0.55 \}$$

 ρ : reflection coefficient

s: specular reflection factor

 $\varepsilon_{\rm f}$ and $\varepsilon_{\rm b}$: emission coefficients of the front and back side, respectively

 $B_{\rm f}$ and $B_{\rm b}$: non-Lambertian coefficients of the front and back side, respectively

Simulation Model

Considerations for high-precision trajectory control:

- Solar sail bends and wrinkles, depending on actual solar sail design
- Gravitational forces of all celestial bodies
- Reflected light from close celestial bodies
- Solar wind
- Finiteness of solar disk
- Finite low-precision attitude control maneuvers
- Aberration of solar radiation (Poynting-Robertson effect)

Allowed simplifications for mission feasibility analysis:

- Solar sail is a flat plate
- Solar sail is moving under sole influence of solar gravitation and radiation

- Sun is a point mass and a point light source
- Solar sail attitude can be changed instantaneously

 normal direction

e: eccentricity

f: true anomaly

h: orbital angular momentum per spacecraft unit mass

 \mathbf{k} : direction vector

p: semilatus rectum

r: radius

 $\omega\colon$ argument of perihelion

Now it is clear that to decrease the semi-major axis with a maximum rate, the thrust vector has to be along the direction $-\mathbf{k}_a$ (local steering law \mathcal{L}_{a^-}). To increase the inclination with a maximum rate, the thrust vector has to be along the direction \mathbf{k}_i (local steering law \mathcal{L}_{i^+})

Hot Mission Scenario

Summary and Conclusions

Evolutionary Neurocontrol (ENC)

A smart global trajectory optimization method

- We used ENC to calculate near-globally optimal trajectories
- ENC is based on a combination of artificial neural networks with evolutionary algorithms
- ENC attacks trajectory optimization problems from the perspective of artificial intelligence and machine learning
- ENC was implemented within a low-thrust trajectory optimization program called InTrance (Intelligent Trajectory optimization using neurocontroller evolution)
- InTrance requires only the target body/state and intervals for the initial conditions as input to find a near-globally optimal trajectory for the specified problem
- InTrance works without an initial guess and does not require the attendance of a trajectory optimization expert

Determination of the SPI Trajectory Using Local Steering Laws

Using LSLs, the strategy to attain the SPI target orbit divides the trajectory into the following phases:

- Spiralling inwards until the SPI target semi-major axis is reached (using local steering law L_a)
- 2: Cranking the orbit until the SPI target inclination is reached (using local steering law \mathcal{L}_{i^+})
- 3: Circularizing the orbit until the SPI target orbit is attained (using a combination of the local steering laws \mathcal{L}_{a^-} , \mathcal{L}_{a^+} , and \mathcal{L}_{e^-})

Summary and Conclusions

Summary and Conclusions

- A current SPI reference mission design employs a cold mission scenario, where the sail film temperature stays colder than 100°C (a quite conservative value). It spirals inwards to 0.48 AU and then cranks the orbit to 75 deg (transfer time is 6.9 years for $C_3 = 0 \text{ km}^2/\text{s}^2$)
- Using this temperature limit as a direct constraint (instead of a solar distance limit), we have found a faster transfer trajectory (6.4 years) that approaches the sun to about 0.4 AU solar distance and thus better exploits the solar radiation pressure
- For hot mission scenarios (higher sail temperature limits of 200-260°C), the optimal transfer trajectories approach the sun even closer (to about 0.20-0.26 AU solar distance), resulting in even shorter transfer durations (4.5-4.9 years)
- We have also performed various tradeoffs for the hot mission scenario to gain a deeper insight into the trade space of the SPI mission and to help the designer of such a mission to estimate the required transfer time

- ► A current SPI reference mission design employs a cold mission scenario, where the sail film temperature stays colder than 100°C (a quite conservative value). It spirals inwards to 0.48 AU and then cranks the orbit to 75 deg (transfer time is 6.9 years for $C_3 = 0 \text{ km}^2/\text{s}^2$)
- Using this temperature limit as a direct constraint (instead of a solar distance limit), we have found a faster transfer trajectory (6.4 years) that approaches the sun to about 0.4 AU solar distance and thus better exploits the solar radiation pressure
- For hot mission scenarios (higher sail temperature limits of 200-260°C), the optimal transfer trajectories approach the sun even closer (to about 0.20-0.26 AU solar distance), resulting in even shorter transfer durations (4.5-4.9 years)
- We have also performed various tradeoffs for the hot mission scenario to gain a deeper insight into the trade space of the SPI mission and to help the designer of such a mission to estimate the required transfer time

Hot Mission Scenario

Summary and Conclusions

SPI Mission Challenges

- The mission performance might be seriously affected by optical degradation of the sail surface, as it is expected in the extreme space environment close to the sun. Due to the unknown degradation behavior of solar sails in the space environment, ground and in-space tests are required
- The hot mission design requires an advanced spacecraft thermal control system that is able to withstand close solar distances
